NAME test-tc.py

Test driver to exercise the tconfpy Python module.

SYNOPSIS

test-tc.py [symtbl] [inmem] [nonewvars] [templates] [temponly] [limitns] [litvars] [nopredefs] [debug] cfgfile, ...

OPTIONS

symtbl This option causes the test driver to include a symbol table with some predefined test variables in it. These are useful for experimenting with variable dereferencing, substitution, and type/value enforcement. The variables created are:

Name	Val	RO	Туре	Def	Legal Values	Min/Max	
int1	1	True	int	0	[1, 2, 23]	None	None
int2	1	True	int	0	[]	1	30
float1	1.0	None	float	0.5	[3.14, 2.73]	None	None
float2	1.0	None	float	0.5	[]	-1.2	0.5
strl "s	stringy"	None	None	None	<pre>[r'^box\$', r'^Bax', r'a+bc']</pre>	3	8
cmplx1	4+5j	None	complex	0-0j	[]	None	None
cmplx2	4+5j	None	complex	0-0j	[1-1j 1+1j]	None	None
bool1	True	None	boolean	None	None	None	None
rol "H	ReadVar"	False	None		None None	None	None

Notice that some of the fields are defined as None. In this case, that parameter is set to its default value when the variable is created. (See the tconfpy documentation regarding the VarDe-scriptor object for the details.)

The default is to not predefine any such variables. (Note that whether this option is present or not, tconfpy always creates a number of predefined variables of its own internally. See the tconfpy documentation for the details.)

You can see all the predefined variables (and their attributes) by running test-tc.py on an empty configuration file. This will show you both the variables automatically defined by tconfpy as well as any variables created with this option, if present.

inmem Read each cfgile specified on the command line into an in-memory list, and pass this list to the parser. This exercises the in-memory parsing capabilities of tconfpy. It is primarily provided as a diagnostic tool for anyone modifying the parser code.

nonewvars

This option disables the creation of new variables in the configuration file (via the AllowNew-Vars API option). The user is limited to referencing and modifying only those variables already present in the symbol table. Typically used when passing an initial symbol table to the parser to limit the user to only those variables. The default is to permit new variable creation.

templates

This option creates a default set of variable templates for use in the configuration file. These are

passed to the tconfpy parser via the Templates={ } API option.

The following variable templates are predefined when this option is used:

Name	Val	RO	Туре	Def	Legal Values	Min/Max	
templb	1	RW	boolean	False	[]	None	None
templc	4+5j	RW	complex	0-0j	[1-1j, 1+1j]	None	None
templf	1.0	RW	float	0.5	[3.14, 2.73]	None	None
templi	1	RW	int	0	[1, 2, 23]	None	None
templs	"stringy"	RW	string		<pre>[r'^box\$', r'^Bax', r'a+bc']</pre>	3	8

temponly

This option will only permit new variable creation if a template for that variable exists (via the TemplatesOnly=True parser API option). This is used in conjunction with the templates option above.

- **limitns** This option will populate the initial symbol table so that only a limited number of namespaces can be used. If this option is present, only the root namespace, and namespaces beginning with the string "NS" will be allowed. In this case, namespaces will be required to be from 3 to 8 characters long. The default without this option is to allow new namespaces to be used without restrictions on name or length. The initial namespace is set to root ("") whether or not this option is selected.
- **litvars** By default, tconfpy does nothing to text encountered inside of .literal blocks in a configuration file. If this option is present, the test driver tells tconfpy to replace any variable references present in a .literal block. See the tconfpy documentation for a more complete description.

nopredefs

This option tells the parser (via the ReturnPredefs=False API option) to **not** include any of its own predefined variables in the symbol table it returns.

debug This option causes the test driver to invoke tconfpy with debugging enabled and then display debug output when parsing is complete. The default is for debug output to be disabled.

ADDING OR CHANGING PREDEFINED VARIABLES IN THE TEST DRIVER

This test driver uses a simple table-driven scheme for predefining variables should you desire this feature. This can be found near the beginning of the test-tc.py file. All this should be fairly self-explanatory once you understand the various variable attributes recognized by tconfpy. Edit this table as desired to create more variables or different attribute values for your testing purposes.

The exact same scheme is used for predefining variable templates and you can add/delete/change these to suit your own tastes in the same way.

OTHER

Requires Python 2.3 or later.

BUGS AND MISFEATURES

The symbol table dump at the end of a program run could be formatted better.

COPYRIGHT AND LICENSING

test-tc is part of the tconfpy package and is Copyright (c) 2003-2005 TundraWare Inc. For terms of use, see the tconfpy-license.txt file in the program distribution. If you install tconfpy on a FreeBSD system using the 'ports' mechanism, you will also find this file in /usr/local/share/doc/py-tconfpy.
